White space and line breaks in program code

Generally, a monospace font is used when printing source code written in C/C++ or Java. Also, as white space has an important meaning in source code, we cannot discard it when printing. Setting the properties font-family="monospace" and white-space="pre" on <fo:block> will preserve the white space in the code and print the white space and text in monospace.

The following example was made simply by pasting the unchanged program code into an <fo:block>:

```
void main(void)
{
    printf("Hello, XML world!");
}
```

white-space="pre" is a shorthand property. It works the same as specifying the following:

linefeed-treatment="preserve"
white-space-collapse="false"
white-space-treatment="preserve"
wrap-option="no-wrap"

When wrap-option="no-wrap" is specified, lines will not be wrapped. To wrap lines, specify wrap-option="wrap" (default value).
