## Example of multi-columns

The second page has two columns and the third page shows an example of three columns.

Another field where XSL is expected to be important is print XML data with layout and output it to PDF.

For example, when we convert form data into XML, it is natural to input data on browser form and specify the data format is XML, output to paper by specifying XML format. Therefore, XML is a tag mapped form, it is necessary for men to understand the contents and confirm XML to print by giving format type, or to output digitalized paper such as PDF.

In this industry, special form printing tool has been popular currently in use. Special

form printing system specifies the special format in the traditional way. While, XSL can specify layouts flexibly by creating world standard stylesheet. As the result, we can develop open system in a short period and at low cost using XSL.

In the future we expect that XSL will expand as an open solution instead of special form printing tool.
