

# List Example

Here is an example of list using `fo:list-block`. The region of list label and list body can be determined by specifying `provisional-label-separation` (the distance between the ending position of a label region and the starting position of a body region), and `provisional-distance-between-starts` (the distance between the starting position of a label region and the ending position of a body region) to `fo:list-block`. In the following example, `provisional-label-separation="1em"` `provisional-distance-between-starts="4em"` is specified with `fo:list-block`.

**Label region** Body region. The length of list label and the start position of the list body can be calculated automatically by specifying `end-indent="label-end()"` in `fo:list-item-label`, `start-indent="body-start()"` in `fo:list-item-body`.
