

Rendering where inline content overflows

Use ‘axf:text-overflow’ to control rendering where inline content overflows in the inline progression direction. ‘axf:text-overflow’ applies to in the inline progression direction and does not affect overflow in the block progression direction. This feature is effective only with `overflow="hidden"`. The allowed values are: ‘clip’ (default: no processing is performed even if an overflow occurs); ‘ellipsis’ (insert an ellipsis (U+2026) where the content overflows); and ‘string’ (insert the specified character string where the content overflows). If the first character overflows, then it is clipped rather than ellipsed. For more details on ‘[axf:text-overflow](#)’, please refer to the Online Manual. ‘axf:text-overflow’ is available in AH Formatter V6.5 and later.
