

List example

This example uses `<fo:list-block>` to format a list. The widths of each list label and list body can be determined by specifying 'provisional-label-separation' (the distance between the ending position of a label area and the starting position of a body area), and 'provisional-distance-between-starts' (the distance between the starting position of a label area and the ending position of a body area) on `<fo:list-block>`.

Label area Body area. The width of the list item label and the start position of the list item body can be calculated automatically by specifying `end-indent="label-end()"` on the `<fo:list-item-label>` and specifying `start-indent="body-start()"` on the `<fo:list-item-body>`.

In the following example, `provisional-label-separation="1em"` and `provisional-distance-between-starts="4em"` are specified on `<fo:list-block>`.
