

line-height-shift-adjustment

The 'line-height-shift-adjustment' property specifies whether to consider the position of superscript and subscript characters (text that has a 'baseline-shift') in the line when determining the line height. When line-height-shift-adjustment="consider-shifts" (default) is specified, the adjusted top edge of superscript characters and bottom edge of subscript characters affect the calculation of the line height. When line-height-shift-adjustment="disregard-shifts" is specified, their 'baseline-shift' has no effect. Note that line-height-shift-adjustment="disregard-shifts" does not affect the line height only for 'baseline-shift'. If there is a factor other than 'baseline-shift' that affects the line height, the line height will change even if the property is specified. For example, when 'font-size' of the character to be shifted is larger than the base text, etc.
